Tutorial 1: Simple movement and dance

Pepper has 20 degrees of freedom throughout its body, an anthropomorphic shape and flexible joints, so Pepper can use those joints to perform a wealth of basic and evocative actions. So how do we get Pepper to move?

1 Uncover the mystery of Animation

Three Animations are actually created by queens and put files.

1.1 What is a qianim file?

A qianim file represents Pepper's basic Animation Library. With these movements, Pepper's image will be more vivid.

1.2 How to create a qianim file

The Animation Recorder module saves enough animations to create animations for the robot. In Android Studio, choose File > New > Import Animation.

The Animation Recorder window will appear

When you select an Animation, a preview of the Animation is displayed on the robot, you can see the light

Select the desired Animation and click "Select", then you can import the Animation into the project. <ctr></ctr>

1.3 What is a put file

The put file represents the Pepper's trajectory. You need to create this file if you want to set the path along which Pepper will move.

1.4 How to create a put file

In Android Studio, select File > New > Animation Trajectory from Control and click "OK" to create the file in the res/ animation/ directory. <ctr></ctr> See Trajectory Editor Tool window will appear.

1. Timeline: Represents the keyframes of the current frame in the path point. The unit selected on the path point. Drag the indicator to set the current time, which is displayed in the lower left corner.

2) Add the properties of the phase you created. Enumerate: reflects the frame, rule, how many frames per second. effect: reluctance should be Pepper's hand movement when the Pepper Motion Service tool rule should be set to the trajectory.

3) Add Keyframe: Allows you to add intermediate points to the current trajectory. When clicked, moving the head point (Pepper's head) to the desired location, and then click Add Keyframe to add a keyframe to the current time.

4) Trajectory Editor: When you are dragging the mouse, you can see the corresponding coordinates or manually set the parameters of the point based on the direction of its path path.

5) Keyframes: Allows you to view the number of time nodes in creation a trajectory.

6) Preview Button: Preview/pause the trajectory.

7) Path Control Program: Enabling you to edit the last point of the trajectory.

8) All Tracks: Allows you to add and adjust trajectories. All trajectories associated with planar motion are shown here, each behind one tracks. Click on the Trajectory Inspector to view and/or trajectory in the current Phase data. Click an empty button to select a trajectory and display it in the edit area. Click and hold the Shift or Ctrl + Click to select multiple trajectories to display them in the same drawing area.

2 Customizing Animation

What if the actions in the sample Animation don't meet the needs of the current time? Don't worry, we can still customize the Animation.

2.1 Create a new Animation Timeline

In Android Studio, select File > New > Animation Timeline.

Enter a name and the Animation Editor window will be blank Animation file will appear.

By default, the Proportional and Cartesian views are displayed.

2.2 Getting to know the Animation Timeline

2.2.1 Frame View

The content of frame view of each row. Frames are the basic components of Animation. equivalent to each frame of a film. For Pepper, a frame holds an action, and connected to frames from Animation. keyframes are frames where the user actively defines the action.

- The green flag indicates the frame where the animation starts
- The blue line marks the selected frame
- The flag indicates the frame where the animation ends

2.2.2 Shortcut Action Toolbar

Above the frame view there is a line for quick access to the toolbar

(1) New Animation

(2) Open Animation

(3) Save Animation

(4) Save Animation As

(5) Undo

(6) Restore Undo

(7) Set the global speed of Animation.

(8) The standard speed of Animation is 100% (frames per second).

To modify the global acceleration speed of Animation, modify the value of the FPS property

- The higher the value, the faster the Animation will play.
- The smaller the value, the slower the Animation plays.

(9) Limiting fluctuations for the whole body

(10) Create the keyframes for the head

(11) Create keyframes for the arms

(12) Move the selected keyframe to the other side.

(13) Copy the selected keyframes to the other side (left to right/right to left)

(14) jumps to the previous keyframe

(15) jumps to the next keyframe

2.2.3 Executor List

On the left is the list of actuators, consisting of Head, LArm, Rarm, Leg, which can be expanded or collapsed.

'Dependent' view ###

'Curves' view

For both views:

- Lock/unlock a previous operation(s) changes on the curve. When activated, the colour of the curve will change to grey and the curve will be locked.
- Show curve: when Animation is added, a default curve will appear on the user and can be expanded.
- AutoKey: allows to create frames by editing the actuator on the Robot 3D view.

Only for 'Curves' view:

- Colour: The colour of each curve is shown next to the actuator name. Click it to select another colour.
- Hide: Hiding some effects curve to simplify the curve view or focus on specific actuators.

2.2.4 Robot 3D View

On the right side is the 3D view of the robot, you can preview the current Animation and modify it. Left mouse button drag: rotate up, down, left, right. Right mouse button drag: pan. Mouse wheel: zoom in and out.

- To display the entire robot based on, use the Reset Camera button on the head of the robot.
- On the Robot 3D view, motion assist can be set manifested round

When enabled, if the robot #ElementRobot is manifested, the value of [ElementRobot] or auto manifested.

The 3Dm aids the regards by holding down the Shift key.

- Actuator value display.

The expected values can be adjusted by dragging the sliders. It is suggested to use from 0 to 1 to the right, or 0 to dragging the actuator related directly.

The colour of the slider controls the value of Animation: whether the expected value has been reached or not. Gamma means that the current value is equal to the last expected value. Blue means that the current value is not the expected value. A blue arrow may be related because it is the command is not expected. If it's the same amount made the expected value (e.g. there is an obstacle).

2.2 Creating the first Animation

The following creates a simple 'Animation' a hand wal.

Define an animation

(1) Select Robot > Position > Stand. this is an initial pose.

(2) Create keyframes for the arms. Select the RArm property cell to be displayed in the Inspector and Curves' view. You can also create them by clicking on the Robot 3D view and dragging the mouse.

Add a new keyframe to create the hand-down action.

(3) Click the new frame according to the Robot 3D view and drag it down corresponding to the time marked in creation in the new actions, for example, Frame = 4. The blue line indicates the selected frame.

(3) On the Robot 3D view, select the hand. Hidden and wheels appear, allowing you to move the hand.

Add a new keyframe to create the hand-up action.

(4) Click another frame, say frame 40, drag the arm up and adjust in RoboPlan slider to raise the hand.

(5) Create the hand action.

Add a new keyframe to create the hand-up action.

(6) Click another frame, say frame 80, drag the arm up and adjust in RoboPlan slider to raise the hand.

(7) Create the hand action.

Test Animation

Choose Robot > Play animation to see the defined Animation on the Robot 3D view.

If we want to test the effect of Animation in real interface

(1) The robot is connected to the network and the connection is successful.

(2) Choose 'Robot > Play animation' or click the 'Play' button on the 'Robot' toolbar

You can see the real robot playing the animation.

At the same time, the message box may increase the currently playing frame

(3) When playing Animation, you can use 'Frame/Restore' and 'Stop' commands in 'Robot' menu and toolbar. Pause/Restore and 'Stop'.

- Save the Animation

Select File > Save.

2.3 Animation Mode

In addition to manually Animation by setting the actuator values as described above, there is a easier intuitive way to create Animation by adjusting the pose of a real robot, which is called Animation Mode. In this mode, the robot behaves like a puppet and the manipulator allowing you to record the pose in the Timeline.

2.3.1 Enabling Animation Mode

(1) Make sure the Animation Editor is connected to a real robot.

(2) Click

Enabling Animation Mode' icon. At this time, Pepper's eyes colour changes to

2.3.2 Defining and Storing Poses

To define and store poses, repeat the following steps for each pose:

(1) Select a frame.

(2) Manipulate the robot's limbs one by one by following the robot's below to keep the robot in the pose you want to store.

- Head - rotate the robot's head by rotating the head sensor in the middle of the head unit.
- Arms - rotate the arm by lifting the **Hand** on the arm and hold the wrist sensor on the **back of the hand**.

Each joint is still when it encounters stiffness and cannot adjust its position. Position adjustment is possible only when moving all the stiffness. Remember that when encountering rigidity by looking at Pepper's eye LED colour.

The rapid speed of the eye drives pauses to indicate that the hand turns off the stiffness and the pose can be adjusted.

The solid speed of the eye drives pauses, it means that the end of the side closes the stiffness, and you can adjust the pose.

(3) Use the 'Edition' menu in the toolbar to create keys:

2.5.3 Exit Animation Mode

Click the

button , or place your hand on the head touch sensor for 3 seconds. The button changes to:

, indicating that the Animation Mode is off.

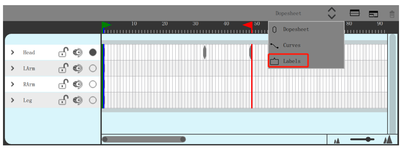
Note: If the Animation Editor disconnects from the robot, Animation Mode will exit automatically.

2.6 Adding Tags

If you want the robot to do something else while executing an Animation, you can define labels through the Label interface. The labels will be saved in the Animation file, and callback events will be triggered by the labels. To add a label, follow the steps below.

Open the Animation file.

Display the Label view.



Click the 'Add group' button. Click the default group name to rename it.

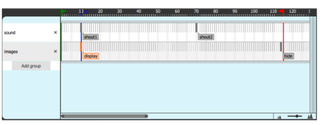
Click on the default group name to rename it. rename_group_name

4, in the timeline, right-click a frame, and then in the menu, select 'Add a labe'.

Add a labe' in the menu.

5, click on the label name can be renamed.

Click on the label name to rename it.



- To delete a label, select the label and press the Delete key.
- To move the label, mouse-click and drag it.

Add the event listener for arriving at the label in the code.

```
animate.addOnLabelReachedListener(new Animate.OnLabelReachedListener() {
    @Override
    public void onLabelReached(String label, Long time) {
        // Called when a label is reached.
        Log.d("TAG", "label name:" + label + ";the label time of occurrence:" + time);
    }
});
```

3 Building an animation

.

3.1 Call the created Animation file and execute Animation

```
Animation myAnimation = AnimationBuilder.with(qiContext)
.withResources(R.raw.dance_b001)
.build();

Animate animate = AnimateBuilder.with(qiContext)
.withAnimation(myAnimation)
.build();

Future<Void> animateFuture = animate.async().run();
animateFuture.thenConsume(future -> {
    if (future.isSuccess()) {

    } else if (future.isCancelled()) {

    } else if (future.hasError()) {

    }
});
```

Where: dance_b001 is the name of the resource file (qianim file or pmt file), which can be changed according to the name of the file you created.

3.2 Listening to Animation events ### When we want to start an Animation, we need to listen to the events of the Animation.

When we want to talk or play music when the Animation starts executing, we need to add an event listener for the Animation to start executing, so that we can execute the talk or play music in the callback.

```
animate.addOnStartedListener(new Animate.OnStartedListener() {
    @Override
    public void onStarted() {

    }
});
```

3.3 Stopping Animation

```
animateFuture.requestCancellation();
```

4 Connecting to a real robot

If the Animation Editor is already connected to a real robot, the connect button is displayed as

instead of

.

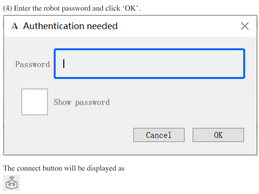
(1) If you are not connected to the real robot, make sure the robot is turned on, select 'Robot' > 'Connect to/disconnect from Robot', or click

button.

(2) Make sure the port is **9503**.

(3) Enter the IP address of the robot (clicking the Pepper chest button will broadcast the IP address) and click 'Connect'.

(4) Enter the robot password and click 'OK'.



The connect button will be displayed as

.

After connecting the Animation Editor to a real robot, you can control the real robot from the Animation Editor:

5 Precautions for using Animation

Pepper will automatically avoid obstacles when executing Animation, and if an obstacle prevents him from safely completing the entire Animation, the Animation will be partially executed. If Pepper encounters an obstacle along the way while executing a trajectory, he will avoid the obstacle and try to execute the trajectory as accurately as possible, but the total time of the Animation remains the same.

2、When there is already an Animation running, it can't run another Animation at the same time, Pepper has many APIs related to Animation, such as Say (BodyLanguageOption is not disabled by default), LookAt, so it can't execute an Animation when calling these APIs. Animation.
